

Exercise 2

The `#pragma omp single` command specifies that the enclosed block of code is to be executed by exactly one thread in the parallel team. Whichever thread reaches this block first will execute it, while the other threads bypass it. Additionally, there is an implicit barrier at the end of a single block. This means the other threads will wait at the end of the block until the single executing thread has finished it, ensuring that no thread moves on to the "Hi again" statement until the single block is completely resolved.
